

Use of Renewable Energy Sources (RES) on Rooftops of Existing Buildings in the City Center

Description

The purpose of this project is to develop a fast and low-cost digital lead-qualification tool for photovoltaic (PV) system companies, eliminating the need for time-consuming on-site inspections. Utilizing **QGIS** software, I accurately mapped building rooftops at the city-block level and automatically calculated their net surface area. The system automatically ranks buildings based on their available surface area, enabling the company's sales department to immediately identify "target buildings" with the highest profitability potential and panel capacity. This specific methodology is fully scalable and can be directly applied at a municipal or regional level for mass customer acquisition.

This digital tool solves four of the major challenges that PV companies face during the client acquisition process:

1. **Drastic Cost & Time Reduction:** It eliminates the need for preliminary on-site inspections by engineers. The sales department knows the rooftop capacity before even contacting the owner.
2. **Conversion Rate Optimization (High-Yield Targeting):** It enables smart data filtering. The company can isolate and target exclusively buildings with rooftops exceeding, for example, 150m², ensuring that sales representatives dedicate time only to high-potential, profitable leads.

3. **Mass Lead Generation:** Instead of random searching, this method allows for the scanning of entire industrial zones or urban areas. It instantly generates a ready-to-use prospect list sorted from the largest to the smallest project.
4. **Personalized Proposal Preparation:** Before the initial contact, the salesperson possesses the exact surface area data. Consequently, they can present an initial estimate regarding the number of panels and the capacity (kW) that can be installed, making the pitch highly compelling.
